

**Early Intervention
for Children with
Autism Spectrum
Disorders:
*Guidelines for
Best Practice***

Margot Prior
and
Jacqueline Roberts
2006

Autism is a severe neurodevelopmental disorder beginning at birth or shortly after. The characteristic symptoms have been described as a triad of impairments involving delay and deviance in social and communication development, along with restricted interests and repetitive behaviours. The term Autism Spectrum Disorders (ASD) covers diagnostic labels which include Autistic Disorder, High Functioning Autism, Asperger Syndrome, and Pervasive Developmental Disorder – Not Otherwise Specified (PDD-NOS). Children with these labels all share the social and communicative symptoms which are the core of autism, but they vary in severity of symptoms and in level of functioning. No specific cause has yet been identified although there is evidence that autism may be inherited to a degree in some cases. To help children with autism it is essential to focus on the earliest years of development, since this is a critically important time for early learning which powerfully affects the child's future life course.

A review of early intervention (EI) services for children with autism was undertaken by the authors during 2006 for the Commonwealth Department of Health and Aging, to evaluate the evidence of the value of the available intervention programs. The review can be found on the DoHA website.

Roberts, J. M. A., & Prior, M. (2006).

A review of the research to identify the most effective models of practice in early intervention of children with autism spectrum disorders. Australian Government Department of Health and Ageing, Australia.

This booklet provides: a summary comment on research findings relating to early intervention for autism; an outline of the kinds of programs available in Australia; research and evidence based guidelines for best practice in early intervention; and a list of contacts for programs across Australia.

Evidence based treatment guidelines are particularly important in the field of autism where there has been so much debate, and where there are many heavily promoted approaches for which there is no scientific evidence, and which can even be harmful.

Intensive educational and behavioural interventions have produced positive outcomes for children with autism. There is little supporting evidence for other kinds of programs, or for medical or drug treatment. Some drugs may help in treating particular symptoms such as agitation and aggression in some children, but none can 'cure' autism. Many families are choosing to try a variety of alternative therapies, but there is no scientific evidence that any of these can make a significant difference. Information about biologically based interventions can be found in the review (Roberts and Prior, 2006). A summary of various kinds of educational and behavioural interventions is provided in the adjacent table.

Educational Interventions (see full table in the review document)

Type of program
<p>Behavioural Interventions Focus on application of learning theory and skill development. Use Applied behaviour Analysis (ABA)</p>
<p>Developmental Interventions Focus on building relationships and development of social emotional capacities. Example; Relationship Development Intervention (RDI)</p>
<p>Therapy based Interventions Focus on communication and social development or sensory motor development. Usually designed for use with other interventions. Example; Picture Exchange Communication System (PECS), Auditory Integration Training (AIT).</p>
<p>Combined Interventions Incorporate behavioural and developmental strategies. Often include sensory issues. Focus on working with and managing the characteristics of autism. Example; TEACCH (Treatment and Education of Autistic and related Communication handicapped Children)</p>
<p>Other Interventions Example; Music Intervention Therapy</p>
<p>Family Based Interventions Focus on working with families to develop skills in working with their children. Example; The Hanen Program</p>

The most systematic evidence available has come from evaluations of intensive behaviour intervention programs, such as The Lovaas program which uses Applied Behaviour Analysis (ABA) including Discrete Trial Training (DTT). These evaluations have shown improved learning and behavioural development in a significant proportion of children. However these methods do not suit all children and families, and strict conditions of timing, intensity, and quality of therapist training influence the success of these methods. Other programs have so far not provided sufficient evidence of short or long term improvement to qualify for unreserved support.

Reviews of programs available internationally for children with autism are cautious in their conclusions about longer term outcomes for the children, in social, adaptive or vocational areas, or greater independence in adulthood. There are too few well controlled studies to allow for confident claims about what types of intervention are best for improving long term learning and adaptive functioning into adulthood.

We can define the key common elements which are necessary for effective intervention. Effective intervention provides:

- An autism specific curriculum content focusing on attention, compliance, imitation, language, and social skills.
- Highly supportive teaching environments which deal with the need for predictability and routine, and with challenging behaviour, obsessions, and ritual behaviours.

- Support for children in their transition from the preschool classroom.
- Support for family members including partnership with professionals involved in treatments.

Number of hours of treatment per week

To be successful EI needs to be extensive and intensive. A minimum of 20 hours a week over two or more years is essential for young children to make major gains.

Individual Variation

It is important to account for the whole spectrum of autism disorders and to recognise that no one child with autism will have the same pattern of strengths and needs as another. In addition, families differ in their goals, strengths, and needs.

Hence, no one program will suit all children with autism and their families.

There are benefits from early, intensive, family-based treatment programs, so long as these are adapted to the child's pattern of strengths and weaknesses and take account of family circumstances

BEST PRACTICE GUIDELINES

Reference to the guidelines presented here will help parents, carers and professionals to judge the value of programs for children with autism.

It is not our role to recommend any specific program. We provide a set of guidelines to interventions of value, which can help in decision making about the suitability of any program on offer for children with autism.

Recommendations for best practice in Early Intervention

i) Preparation

All children on entering intervention programs should have had a comprehensive, multidisciplinary diagnostic assessment from an interdisciplinary team of experienced clinicians based on national and internationally agreed criteria. Diagnostic evaluations should include;

- interviews with parents/care givers to review the child's developmental history, family history, previous assessments and interventions;
- collection of information from all professionals involved in the care of the child;
- paediatric, psychological, and speech pathology examinations to assess communication, relevant health conditions including motor skills, vision, and hearing, and any associated problems such as intellectual disability and anxiety.

Direct observation of the child is important in the assessment of cognitive, social, communicative (verbal & nonverbal), fine and gross motor, and adaptive functioning with standardised tests and informal procedures. The assessment should detail the child and family strengths and areas of need, to guide the development of intervention and management plans. With very young children, re-assessment and review within a year is desirable, since behaviour may change and the effects of intervention need to be monitored.

Recommendations from the assessment, and implications for intervention support should be combined in a comprehensive written report presented to the family. Contact and consultation with potential intervention program providers needs to be part of this process. Entry to an intervention program should follow as soon as possible following the assessment and diagnostic evaluation.

ii) Timing

Intervention should begin as early as possible in the child's life, (optimally between 2 and 4 years).

iii) Process

All children should have an Individual Plan (IP), for their education, designed to best fit their needs and strengths, developed in consultation with parents, and reviewed and revised regularly in light of the child's progress and ongoing needs

iv) Intensity

A program needs to be of at least 20 hours per week over an extended period of at least two years, with continuing support into, and through the school age years.

v) Content and focus

Autism specific content including:

Teaching joint attention skills, play, and imitation skills.

Building functional communication skills through language and Alternative and Augmentative Communication (AAC) such as picture systems, gestures and signs.

Teaching social interaction skills in a supported environment.

Daily Living skills, e.g. toileting, washing hands, eating.

Management of sensory issues.

Generalization of learning strategies to new situations and with new people

Management of undesirable or challenging behaviours.

vi) Settings

Programs can be delivered in various settings, individually, and with peers. Both centre-based and individual/home-based interventions are valuable. Including typically developing peers for at least a part of the program is highly desirable but peer interaction needs to be supported.

vii) Program design and methods

A high degree of structure in the program is essential, i.e. well organized, regular and predictable, focused on specific objectives, and consistently managed.

A supportive teaching environment with modelling, prompting, praise, shaping, and generalization strategies will maximise learning.

Centre based programs require a low child/staff ratio with a maximum of 2-4 children per adult.

viii) Problem behaviours

A functional approach to problem behaviours including positive behaviour support (PBS) which includes teaching alternative appropriate skills and communication skills to replace the problem behaviours.

ix) Staffing

Teachers, therapists, and child-care personnel should be specifically trained in working with children with autism and have knowledge and skills required for their special needs.

x) Family collaboration

Parents need information about autism and services, especially at key times like first diagnosis and school entry. Programs should include parent involvement, such as provision of support, counselling, and parent education to help the child with play, social, and communication skills development, and with management of challenging and repetitive behaviours.

Families are often in need of respite care, hence reliable provision for this service is essential to decrease family burden and stress.

xi) Associated therapies

Multidisciplinary collaborative teams including specialist support such as speech therapy, occupational therapy and counselling should be available as needed.

xii) Research and evaluation of program

Evaluation of treatment outcomes should be built into EI programs using systematic assessment of the child's social, cognitive, and adaptive functioning before, during, and at the end of the program.

xiii) Transition

There should be systematic connection and integration between the early intervention program and the next stage for the child, whether it is transition to school or to another therapeutic or special educational setting. Parents, teachers and therapists need to collaborate in preparing the child for transition.

Interventions for Infants

Recognising and diagnosing autism before pre-school age has been uncommon until the last few years. But increasingly autism is being identified very early in development. It has been shown that diagnosis can be valid and reliable at 2 years of age, and signs can be recognisable and predictive of autism even from early in the second year of life. In future it is likely that autism will be diagnosed for

most children in the toddler age period (18 - 30 months). Very early therapeutic intervention is likely to improve developmental and adaptive outcomes so it will be necessary to develop, implement and evaluate interventions for this age group in Australia. Trials of interventions in the USA and UK are focusing on training parents to work with their very young children in the key areas of social responsiveness, attention skills, early communication skills, and interactive play.

Information families need. Families should ask for more than personal stories of treatment success when deciding which intervention programs would be safe and beneficial for their child. When considering a program for your child use the information provided in this booklet to determine the extent to which the program meets recommended guidelines.

INTERVENTION SERVICES FOR CHILDREN WITH AUTISM AND THEIR FAMILIES IN AUSTRALIA

Please note that while every effort was made to ensure this information is as accurate, up to date and comprehensive as possible, there may be services which are not included. See review for information about program costs, type, waiting times, staff training and more.
